Policy
Commercial Members: Managed Care (HMO and POS), PPO, and Indemnity Medicare HMO BlueSM and Medicare PPO BlueSM Members

Heart-lung transplantation may be MEDICALLY NECESSARY for carefully selected patients with end-stage cardiac and pulmonary disease including, but not limited to, one of the following diagnoses:
- Irreversible primary pulmonary hypertension with heart failure or
- Non-specific severe pulmonary fibrosis or
- Eisenmenger complex with irreversible pulmonary hypertension and heart failure or
- Cystic fibrosis with severe heart failure or
- Chronic obstructive pulmonary disease with heart failure or
- Emphysema with severe heart failure, or
- Pulmonary fibrosis with uncontrollable pulmonary hypertension or heart failure.

Heart/lung retransplantation after a failed primary heart/lung transplant may be considered MEDICALLY NECESSARY in patients who meet criteria for heart/lung transplantation.

Heart/lung transplantation is considered INVESTIGATIONAL in all other situations.

In addition to the above information, we do not cover heart/lung transplantation when any of the following conditions are present:
- Known current malignancy, including metastatic cancer
- Recent malignancy with high risk of recurrence
  - Note: the assessment of risk of recurrence for a previously treated malignancy is made by the transplant team; providers must submit a statement with an explanation of why the patient with a recently treated malignancy is an appropriate candidate for a transplant.
• Untreated systemic infection making immunosuppression unsafe, including chronic infection
• Other irreversible end-stage disease not attributed to heart or lung disease
• History of cancer with a moderate risk of recurrence
• Systemic disease that could be exacerbated by immunosuppression
• Psychosocial conditions or chemical dependency affecting ability to adhere to therapy

Harvesting of the donor’s organ is **MEDICALLY NECESSARY** when the donor is not a member, as long as the recipient is a member. Harvesting is defined to include the surgical removal of the donor’s organ and related medically necessary services and/or tests that are required to perform the transplant itself.

**Prior Authorization Information**
Pre-service approval is required for all inpatient services for all products. See below for situations where prior authorization may be required or may not be required for outpatient services.
Yes indicates that prior authorization is required.
No indicates that prior authorization is not required.
N/A indicates that this service is primarily performed in an inpatient setting.

Medicare Managed Care and Medicare PPO members, who meet the coverage criteria for heart-lung transplantation, must be referred to a Medicare certified transplant facility.

**Medicare Certified Transplant Facilities:**

**CPT Codes / HCPCS Codes / ICD Codes**
Inclusion or exclusion of a code does not constitute or imply member coverage or provider reimbursement. Please refer to the member’s contract benefits in effect at the time of service to determine coverage or non-coverage as it applies to an individual member.

Providers should report all services using the most up-to-date industry-standard procedure, revenue, and diagnosis codes, including modifiers where applicable.

Description

Combined heart/lung transplantation is intended to prolong survival and improve function in patients with end-stage cardiac and pulmonary diseases. Most recipients have Eisenmenger syndrome (37%), followed by idiopathic pulmonary artery hypertension (28%) and cystic fibrosis (14%). Eisenmenger syndrome is a form of congenital heart disease in which systemic-to-pulmonary shunting leads to pulmonary vascular resistance. Eventually, pulmonary hypertension may lead to a reversal of the intracardiac shunting and inadequate peripheral oxygenation, or cyanosis.\(^1\)

However, the total number of patients with Eisenmenger syndrome has been declining in recent years, as a result of corrective surgical techniques and improved medical management of pulmonary hypertension. Heart/lung transplants have not increased appreciably for other indications either, as it has become more common to transplant a single or double lung and maximize medical therapy for heart failure, rather than perform a combined transplant. In these, patient survival rates are similar to lung transplant rates. Bronchiolitis obliterans syndrome is a major complication; 1-, 5-, and 10-year patient survival rates are 68%, 50%, and 40%, respectively.\(^1\)

In 2014, 24 individuals received heart/lung transplants in the United States. As of the end of October 2015, there were 49 patients on the waiting list for heart/lung transplants.\(^2\)

Summary

Heart/lung transplantation involves a coordinated triple operative procedure consisting of procurement of a donor heart/lung block, excision of the heart and lungs of the recipient, and implantation of the heart and lungs into the recipient. Heart/lung transplantation refers to the transplantation of 1 or both lungs and heart from a single cadaver donor.

The evidence for combined heart/lung transplant in patients who have end-stage cardiac and pulmonary disease includes case series and registry data. Relevant outcomes are overall survival, symptoms, morbid events, and treatment-related morbidity and mortality. The available literature describes outcomes after heart/lung transplantation. Given the exceedingly poor expected survival without transplantation, this evidence is sufficient to demonstrate that heart/lung transplantation provides a survival benefit in appropriately selected patients. It may be the only option for some patients with end-stage cardiopulmonary disease. Heart/lung transplant is contraindicated in patients in whom the procedure is expected to be futile due to comorbid disease or in whom posttransplantation care is expected to significantly worsen comorbid conditions. Based on this evidence and established guidelines, heart/lung transplant may be considered likely to improve outcomes for those who meet clinical criteria and do not have contraindications to the procedure. A very limited amount of data suggest that, after controlling for confounding variables, survival rates after primary and repeat heart/lung transplants is similar. Findings are not conclusive due to the small number of cases of repeat heart/lung transplants reported in the published literature. Repeat heart/lung transplantation may be likely to improve outcomes in patients with a failed prior transplant who meet the clinical criteria for heart/lung transplantation.
