Policy
Commercial Members: Managed Care (HMO and POS), PPO, and Indemnity

Computer-assisted surgery for orthopedic procedures of the pelvis and appendicular skeleton is considered INVESTIGATIONAL.

Medicare HMO BlueSM and Medicare PPO BlueSM Members

This is not a covered service.

Medical necessity criteria and coding guidance for Medicare Advantage members living in Massachusetts can be found through the link below.

Local Coverage Determinations (LCDs) for National Government Services, Inc.

Local Coverage Determination (LCD): Category III CPT® Codes (L33392) (A56195)

Note: To review the specific LCD, please remember to click “accept” on the CMS licensing agreement at the bottom of the CMS webpage.

For medical necessity criteria and coding guidance for Medicare Advantage members living outside of Massachusetts, please see the Centers for Medicare and Medicaid Services website at https://www.cms.gov for information regarding your specific jurisdiction.

Prior Authorization Information
Inpatient
• For services described in this policy, precertification/preauthorization **is required** for all products if the procedure is performed **inpatient**.

**Outpatient**

• For services described in this policy, see below for products where prior authorization **might be required** if the procedure is performed **outpatient**.

### CPT Codes / HCPCS Codes / ICD Codes

*Inclusion or exclusion of a code does not constitute or imply member coverage or provider reimbursement. Please refer to the member’s contract benefits in effect at the time of service to determine coverage or non-coverage as it applies to an individual member.*

*Providers should report all services using the most up-to-date industry-standard procedure, revenue, and diagnosis codes, including modifiers where applicable.*

### Description

**Implant Alignment for Knee Arthroplasty**

For total knee arthroscopy, malalignment is commonly defined as a variation of more than 3° from the targeted position. Proper implant alignment is believed to be an important factor for minimizing long-term wear, the risk of osteolysis, and loosening of the prosthesis.

**Computer-Assisted Navigation**

The goal of computer-assisted navigation is to increase surgical accuracy and reduce the chance of malposition.

In addition to reducing the risk of substantial malalignment, computer assisted navigation may improve soft tissue balance and patellar tracking. Computer assisted navigation is also being investigated for surgical procedures with limited visibility such as placement of the acetabular cup in total hip arthroplasty, resection of pelvic tumors, and minimally invasive orthopedic procedures. Other potential uses of computer assisted navigation for surgical procedures of the appendicular skeleton include screw placement for fixation of femoral neck fractures, high tibial osteotomy, and tunnel alignment during the reconstruction of the anterior cruciate ligament.

Computer assisted navigation devices may be image-based or non-image-based. Image-based devices use preoperative computed tomography scans and operative fluoroscopy to direct implant positioning. Newer non-image-based devices use information obtained in the operating room, typically with infrared probes. For total knee arthroscopy, specific anatomic reference points are made by fixing signaling transducers with pins into the femur and tibia. Signal-emitting cameras (eg, infrared) detect the reflected signals and transmit the data to a dedicated computer. During the surgery, multiple surface points are taken from the distal femoral surfaces, tibial plateaus, and medial and lateral epicondyles. The femoral
head center is typically calculated by kinematic methods that involve the movement of the thigh through a
series of circular arcs, with the computer producing a 3-dimensional model that includes the mechanical,
transsepticondylar, and tibial rotational axes. Computer assisted navigation systems direct the positioning
of the cutting blocks and placement of the prosthetic implants based on the digitized surface points and
model of the bones in space. The accuracy of each step of the operation (cutting block placement, saw
cut accuracy, seating of the implants) can be verified, thereby allowing adjustments to be made during
surgery.

Navigation involves 3 steps: data acquisition, registration, and tracking.

Data Acquisition
Data can be acquired in 3 ways: fluoroscopically, guided by computed tomography scan or magnetic
resonance imaging, or guided by imageless systems. These data are then used for registration and
tracking.

Registration
Registration refers to the ability to relate images (ie, radiographs, computed tomography scans, magnetic
resonance imaging, or patients' 3D anatomy) to the anatomic position in the surgical field. Registration
techniques may require the placement of pins or "fiduciary markers" in the target bone. A surface-
matching technique can also be used in which the shapes of the bone surface model generated from
preoperative images are matched to surface data points collected during surgery.

Tracking
Tracking refers to the sensors and measurement devices that can provide feedback during surgery
regarding the orientation and relative position of tools to bone anatomy. For example, optical or
electromagnetic trackers can be attached to regular surgical tools, which then provide real-time
information of the position and orientation of tool alignment concerning the bony anatomy of interest.

VERASENSE (OrthoSense) is a single-use device that replaces the standard plastic tibial trial spacer
used in total knee arthroscopy. The device contains microprocessor sensors that quantify load and
contact position of the femur on the tibia after resections have been made. The wireless sensors send the
data to a graphic user interface that depicts the load. The device is intended to provide quantitative data
on the alignment of the implant and soft tissue balancing in place of intraoperative "feel."

iASSIST (Zimmer) is an accelerometer-based alignment system with a user interface built into disposable
electronic pods that attach onto the femoral and tibial alignment and resection guides. For the tibia, the
alignment guide is fixed between the tibial spines and a claw on the malleoli. The relation between the
electronic pod of the digitizer and the bone reference is registered by moving the limb into abduction,
adduction, and neutral position. Once the information has been registered, the digitizer is removed, and
the registration data are transferred to the electronic pod on the cutting guide. The cutting guide can be
adjusted for varus/valgus alignment and tibial slope. A similar process is used for the femur. The pods
use the wireless exchange of data and display the alignment information to the surgeon within the
surgical field. A computer controller must also be present in the operating room.
Due to the lack of any recent studies on pelvic tumor resection, these sections of the Rationale were
removed from this evidence review in 2016.

Summary
Computer-assisted navigation in orthopedic procedures describes the use of computer-enabled tracking
systems to facilitate alignment in a variety of surgical procedures, including fixation of fractures, ligament
reconstruction, osteotomy, tumor resection, preparation of the bone for joint arthroplasty, and verification
of the intended implant placement.

For individuals who are undergoing orthopedic surgery for trauma or fracture and receive computer-
assisted navigation, the evidence includes one retrospective clinical trial, reviews, and in vitro studies.
Relevant outcomes are symptoms, morbid events, and functional outcomes. Functional outcomes were
not included in the clinical trial, although it did note fewer complications with computer-assisted navigation versus conventional methods. The evidence is insufficient to determine the effects of the technology on net health outcomes.

For individuals who are undergoing ligament reconstruction and receive computer-assisted navigation, the evidence includes a systematic review of 5 randomized controlled trials (RCTs) of computer-assisted navigation versus conventional surgery for anterior and posterior cruciate ligament. Relevant outcomes are symptoms, morbid events, and functional outcomes. Trial results showed no consistent improvement of tunnel placement with computer-assisted navigation, and no trials looked at functional outcomes or need for revision surgery with computer-assisted navigation. The evidence is insufficient to determine the effects of the technology on net health outcomes.

For individuals who are undergoing hip arthroplasty and periacetabular osteotomy and receive computer-assisted navigation, the evidence includes older RCTs, a systematic review, and comparison studies. Relevant outcomes are symptoms, morbid events, and functional outcomes. Evidence on the relative benefits of computer-assisted navigation with conventional or minimally invasive total hip arthroscopy is inconsistent, and more recent RCTs are lacking. The evidence is insufficient to determine the effects of the technology on net health outcomes.

For individuals who are undergoing total knee arthroscopy and receive computer-assisted navigation, the evidence includes RCTs, systematic reviews of RCTs, and comparative studies. Relevant outcomes are symptoms, morbid events, and functional outcomes. The main difference found between total knee arthroscopy with computer-assisted navigation and total knee arthroscopy without computer-assisted navigation is increased surgical time with computer-assisted navigation. Few differences in clinical and functional outcomes were seen at up to 10 years post-procedure. The evidence is insufficient to determine the effects of the technology on net health outcomes.
